Other ITPs

History

Exact?

```
example (l1 l2 l3 : List Nat) (h1 : l1.length ≤ l2.length) (h2 : l3 = l2) :  
l1.length ≤ l3.length := by  
  exact le_of_le_of_eq h1 (congrArg List.length (id (Eq.symm h2)))
```

Exact? works by

- finding ONE lemma from the list of ALL lemmas ever (uses `DiscrTree`)
- dealing with the remaining goals using LOCAL hypotheses (uses `SolveByElim`)

Exact?

Local Search

Global Search

Overview

Related Tactics

Other ITPs

History

Exact?

```
example (l1 l2 l3 : List Nat) (h1 : l1.length ≤ l2.length) (h2 : l3 = l2) :  
  l1.length ≤ l3.length := by  
  exact le_of_le_of_eq h1 (congrArg List.length (id (Eq.symm h2)))
```

Exact? works by

- finding ONE lemma from the list of ALL lemmas ever (uses **DiscrTree**)
- dealing with the remaining goals using LOCAL hypotheses (uses **SolveByElim**)

exact	<u>le_of_le_of_eq</u>	<u>h1</u>	<u>(congrArg List.length (id (Eq.symm h2)))</u>
	Global Search (DiscrTree)	Local Search (SolveByElim)	Local Search (SolveByElim)

Option

exact? +grind/+try?

exact? using h₁, h₂

Effect

use **grind** / **try?** as fallback discharger for subgoals

"provides identifiers in the local context that must be used"

Fun fact - in Lean 3, `exact?` used linear search!

“`library_search` is just a linear search over the entire environment. We do a tiny bit of filtering, but in the end `apply` is so incredibly fast (in particular, it fails fast) that mostly it is better to just hand everything over to it. I was shocked when I first tried it out that an approach as dumb as that was actually viable.”

Kim Morrison, 2021

Other ITPs

History

Term indexing was used in the early days of automated deduction, but it was undocumented or not emphasized in the literature, and the methods are not well known. As a result, it appears that several of the methods were ‘reinvented’. The origins of the two indexing methods remain uncertain. The roots of discrimination-tree indexing appear to lie directly in formula manipulation systems, and the roots of path indexing appear to lie in database technology.

“Experiments with Discrimination-Tree Indexing and Path Indexing”

William McCune, 1990

Path Indexing

Discrimination Tree

Path Indexing

Our mathlib:

Theorem Name	Statement	Prefix Form
<code>add_2_2</code>	$2 + 2 = 4$	$= (+(2, 2), 4)$
<code>add_2_666</code>	$2 + 666 = 668$	$= (+(2, 666), 668)$
<code>add_3_5</code>	$3 + 5 = 8$	$= (+(3, 5), 8)$
<code>add_3_7</code>	$3 + 7 = 10$	$= (+(3, 7), 10)$
<code>le_of_le_of_eq</code>	$a \leq c$	$\leq (*, *)$

• Linear Search

• Indexing

• Example

Overview

Related Tactics

Other ITPs

History

Path Indexing

Our mathlib:

Theorem Name	Statement	Prefix Form
<code>add_2_2</code>	$2 + 2 = 4$	<code>= (+ (2, 2), 4)</code>
<code>add_2_666</code>	$2 + 666 = 668$	<code>= (+ (2, 666), 668)</code>
<code>add_3_5</code>	$3 + 5 = 8$	<code>= (+ (3, 5), 8)</code>
<code>add_3_7</code>	$3 + 7 = 10$	<code>= (+ (3, 7), 10)</code>
<code>le_of_le_of_eq</code>	$a \leq c$	<code>≤ (*, *)</code>

Each theorem generates a number of "paths".

Each "path" has the form `[symbol, arg-position, symbol, arg-position, ..., symbol]`.

For example, `add_3_7`: `= (+ (3, 7), 10)` has five symbols, so it generates five paths:

Symbols (<code>add_3_7</code>)	Path
<code>=</code>	<code>[=]</code>
<code>+</code>	<code>[=, 1, +]</code>
<code>3</code>	<code>[=, 1, +, 1, 3]</code>
<code>7</code>	<code>[=, 1, +, 2, 7]</code>
<code>10</code>	<code>[=, 2, 10]</code>

History

Per each theorem, per each symbol: compute its path:

Symbols (add_3_7)	Path
=	[=]
+	[=, 1, +]
3	[=, 1, +, 1, 3]
7	[=, 1, +, 2, 7]
10	[=, 2, 10]
Symbols (add_3_5)	Path
=	[=]
+	[=, 1, +]
3	[=, 1, +, 1, 3]
5	[=, 1, +, 2, 5]
8	[=, 2, 8]

And put those paths into a new table:

Path	add_3_5	add_3_7
[=]	✓	✓
[=, 1, +]	✓	✓

Suppose our goal is $3 + 7 = 10$.

Compute the path of each symbol of our goal, and intersect the theorem sets:

[=]	$\{\text{add_3_5}, \text{add_3_7}\}$
[=, 1, +]	$\cap \{\text{add_3_5}, \text{add_3_7}\}$
[=, 1, +, 1, 3]	$\cap \{\text{add_3_5}, \text{add_3_7}\}$
[=, 1, +, 2, 7]	$\cap \{\text{add_3_7}\}$
[=, 2, 10]	$\cap \{\text{add_3_7}\}$
	$= \{\text{add_3_7}\}$

Path Indexing

Discrimination Tree

We found our theorem candidate: **add_3_7**.

```
graph TD; A[Indexing Theorems] --> B[Path Indexing]; A --> C[Discrimination Trees];
```

Path Indexing

Discrimination Trees

Two different indexing methods are used: discrimination-tree indexing and path indexing. Some types of term are much better handled by one or the other of the indexing methods. Thus, no clear winner existed between the two methods.

...

The strongest conclusion from the experiments is that discrimination indexing is a clear winner over path indexing for generalization retrieval on the types of term with which I experimented.

“Experiments with Discrimination-Tree Indexing and Path Indexing”
William McCune, 1990

Discrimination Trees

This is our discrimination tree, aka `DiscrTree`.

Lean and Mathlib maintain around 15 different `DiscrTree`s. Nodes always contain Lean expressions, leaves contain different stuff.

`DiscrTree  $\alpha$` : nodes are expressions, each leaf is `$\alpha$` .

`DiscrTree Name` : nodes are expressions, each leaf is a `Name`

`DiscrTree SimpTheorem` : nodes are expressions, each leaf is a `SimpTheorem`

Global Search: Example

Our Mathlib:

```
theorem Nat.add_comm :  $\forall (n\ m : \text{Nat}), n + m = m + n$   
theorem Nat.zero_le :  $\forall (n : \text{Nat}), 0 \leq n$   
theorem Nat.le_refl :  $\forall (n : \text{Nat}), n \leq n$   
theorem Nat.le_succ :  $\forall (n : \text{Nat}), n \leq n.\text{succ}$ 
```

Our goal:

```
⊢ 0 ≤ 5
```

We call `exact?`, and the global search among all Mathlib lemmas starts:

- ▶ We convert each Mathlib theorem into `[Key, Key, Key]`, and put all theorems into a **DiscrTree**
- ▶ We convert our goal into `[Key, Key, Key]`
- ▶ We match the resulting **DiscrTree** to our goal!

Global Search: What We Do To Mathlib

`apply?` and `exact?` call the same function (*/Lean/Elab/Tactic/LibrarySearch.lean*)

- `exact?` calls `exact? ref config required requireClose := True`
- `apply?` calls `exact? ref config required requireClose := False`

```
let newGoals ← goal.apply lemma that matched our goal in DiscrTree
-- lemma is guaranteed to be returned whatever happens to the remaining subgoals
for goal in newGoals do
  let _ ← solveByElim goal
```

Related Tactics: Rw?

- Builds the `DiscrTree` **only** from theorems of the form `x = y` or `x ↔ y`
- Puts **both sides** into the `DiscrTree`:

`x` 's `[Key, Key, Key]` $\rightarrow$ `DiscrTree` (for `rw [lemma]`)

`y` 's `[Key, Key, Key]` $\rightarrow$ `DiscrTree` (for `rw [← lemma]`)

- Subdivides our goal into **all subexpressions**,
and matches all of them to the `DiscrTree` one by one

A **vscode widget** by Jovan Gerbscheid.

You write `rw??`, then **shift-click** any subexpression in the goal.
The widget shows all rewrites for that exact expression.

Uses a **RefinedDiscrTree**.

Other Proof Assistants

	Search Engine	exact?	rw?
Lean	<code>#loogle</code> (command)	<code>exact?</code> / <code>apply?</code>	<code>rw?</code> / <code>rw??</code>
Rocq	<code>Search</code> (command)	<code>auto</code> (production tactic!) ▶ similar to our <code>solve_by_elim</code>, except does consider nonlocal lemmas ▶ we specify a "hint db" (doesn't index whole library) ▶ backtracking with depth 5	—
Isabelle	<code>find_theorems</code> (command)	<code>solve_direct</code> ▶ similar to our implementation ▶ but uses linear search (even though isabelle does have discr trees elsewhere) ▶ and uses the equivalent of our <code>assumption</code> to discharge the goals	—
